A Regulatory Toy Model

- The Model
- Network structure
- Network dynamics
- Heterochronic control
- Evolution
- Stability, communication

Joint work with Dwight Kuo and Andre Leier

The Model: Genome

A simple model of interaction between genes and proteins

Linear Genome → Reading direction

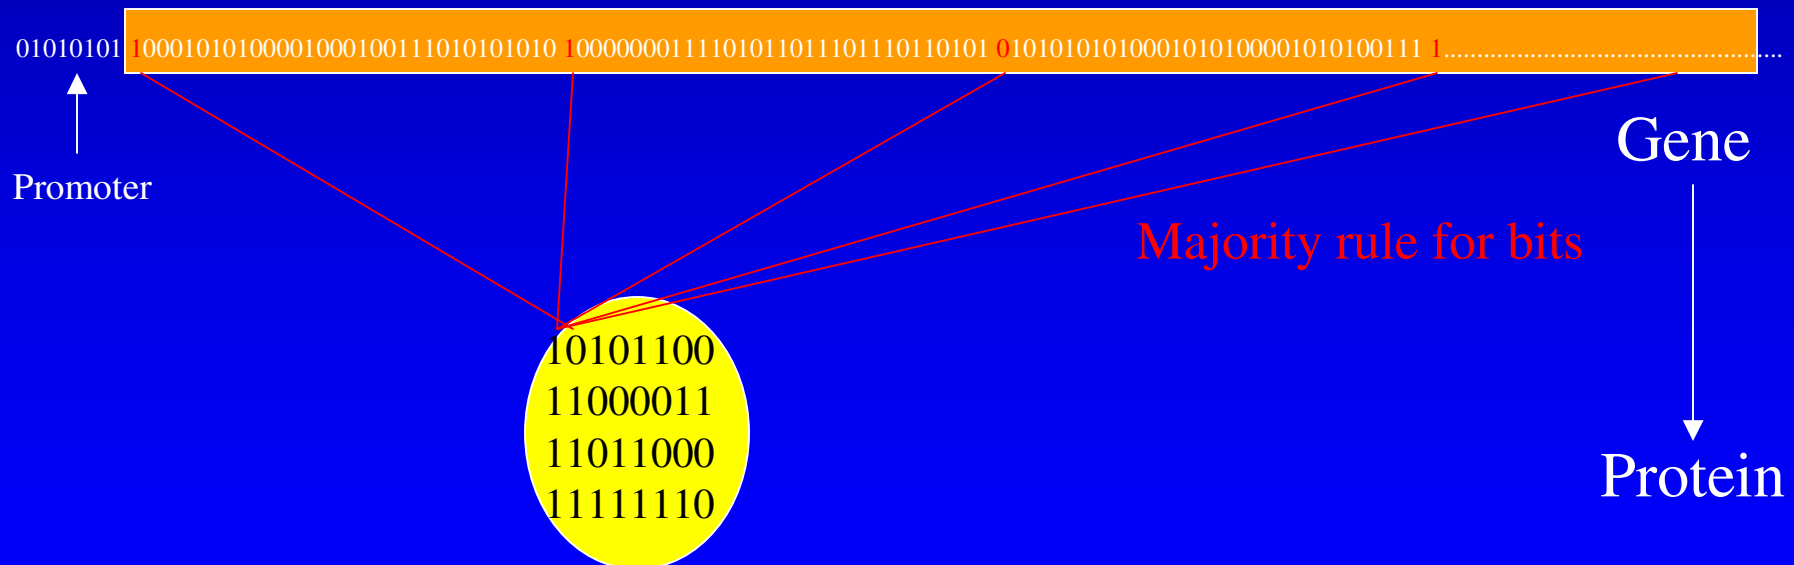

- Gene, including promoter site
- Protein
- Enhancer Site, upstream from gene
- Inhibitor Site, upstream from enhancer

The Model: Proteins from Genes

Gene: Bit string of fixed length (5 x 32 bits)
Protein: Bit string of fixed length (1 x 32 bits)
Promoter: 8 bit sequence 01010101
Probability of promoter and gene: $2^{(-8)} = 0,39 \%$

Genotype – Phenotype Mapping (Many-to-one-mapping)

The Model: Genome-Protein-Interaction

- Both, proteins and genome made from the same material: bit strings
- 32-bit segments might form complementary segments
- Complementarity controls interaction (binding) in a non-linear way

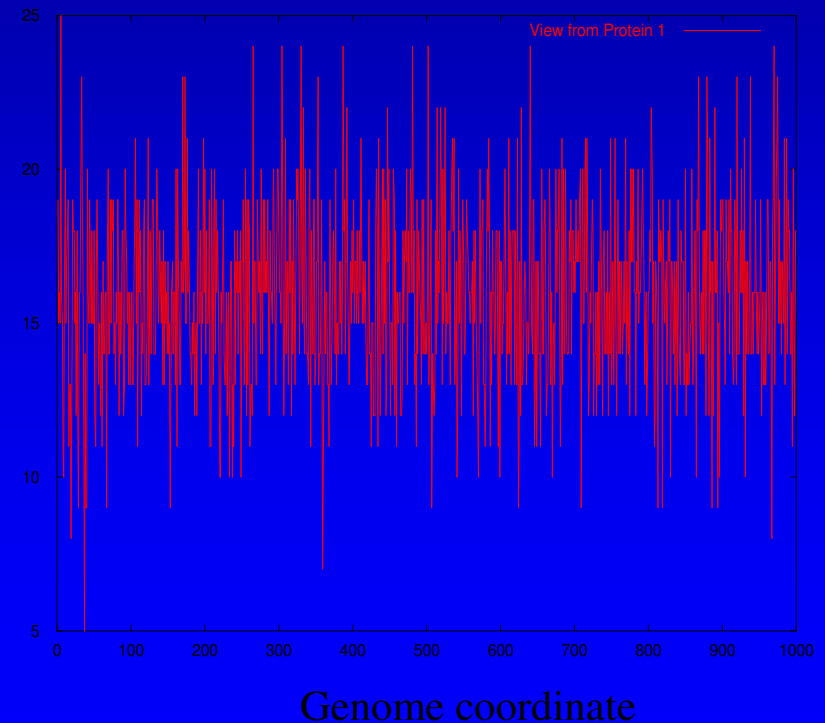

Example: View from Protein

- Complementarity of random genome (1000 x 32-bit) and a protein
- Viewed from the protein perspective

- Average complementarity: 16
- C_{\min} : 5; C_{\max} =25

Complementarity

Example: View from Protein II

- Distribution of complementarities in random genome (1000 x 32-bit)
- 3 proteins

Example: Specificity

- Specificity of complementarities in random genomes (1000 x 32-bit)
- Appr. constant number of most specific interaction

Genome Length	Number of Genes/Proteins	Max. Compl.	Occurence
1,000	3	25	3
10,000	37	28	4
100,000	409	30	3

Example: View from Genome

Interaction strength of enhancer / inhibitor site with proteins

Example: View from Genome II

The Model: Network View

- Protein binding controls expression of genes.
- The higher the binding affinity, the stronger the control
- Network picture of the resulting interaction
- Difference between various kinds of generation of the (random) genome:
- Fully random genome vs. genome generated by duplication and divergence

Network Example: Genome with 32 genes

C = Complementarity

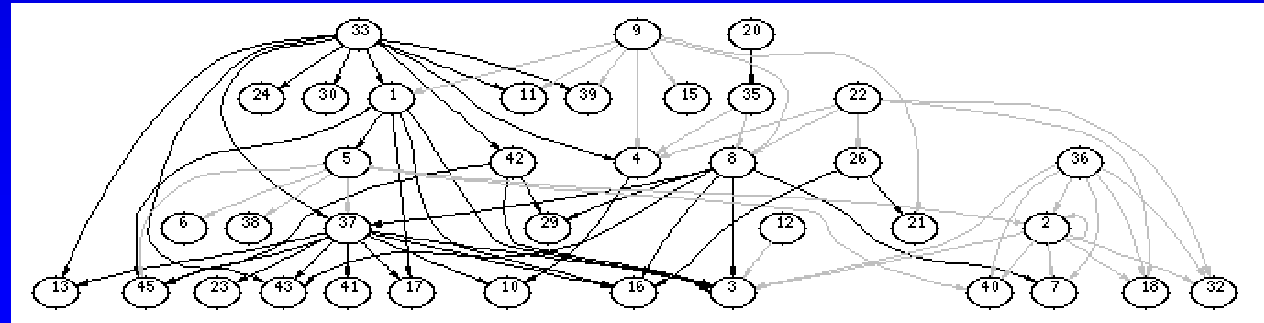

Shown are connections
with $C > 24$

Shown are connections
with $C > 23$

Shown are connections
with $C > 22$

Example for Network View: Genome with 32 genes

Duplication and divergence
Shown are connections with
 $C > 21$

C = Complementarity

Random generation
Shown are connections
with $C > 19$

Network Motifs

- Structural elements (subgraphs) which are basic elements of complex networks
- Certain motifs occur with significantly higher probability than in random networks
- Network Motifs have been shown to be conserved over evolutionary time
- We look at motifs that include feedback-connections

Duplication / Divergence

Random

The Model: Protein-Genome-Interaction

- Protein binding to enhancer / inhibitor sites leads to expression of the site gene.
- Influence on expression of gene is non-linear with binding strength

$$en_i = \sum_j c_j e^{\beta(u_j^+ - u_{\max})} / N$$

$$in_i = \sum_j c_j e^{\beta(u_j^- - u_{\max})} / N$$

with c_j the concentration of protein j and u_{\max} maximum complementarity.

- en and in determine the (competitive) occupation probability of site i
- Both signals contribute to expression of gene i

$$\frac{dc_i}{dt} = \delta(en_i - in_i)c_i - \Phi$$

with Φ a flow term normalizing production of proteins.

The Model: Protein-Genome-Interaction II

3 sorts of competition:

1. Competition of proteins for binding sites
2. Competition of binding sites for proteins
3. Competition of genes for raw material for expression

Example: Protein Dynamics

- Large variety of behavior
 - Oscillations, transient states, point attractor

Run1

Run2

Example: Protein Dynamics II

Run3

Run4

Example: Heterochronic Control

- Certain proteins must be present in particular concentrations at determined moments ($t = 9,500$, $t' = 21,000$)
- These proteins are used to control production of other proteins in turn
- Some of these proteins are used to build structures of the body

Example: Heterochronic Control II

- Single bit flips change timing seriously
- 1 bit mutation: $t=15,000$, $t'=30,000$
- 1 bit mutation: $t=30,000$, $t'=53,000$

Run5: Inh(4,7)+1

Run6 : Inh(4,7)+2

Example: Heterochronic Control III

- Relative shift due to single bit flips

Example: Evolution

Evolutionary problem:

Find a configuration of protein expression levels allowing Protein 6 to be expressed at $C=0.085$

Deviation (Fitness)

Protein Concentrations

Example: Evolution II

- Neutral steps
- Jumps in variation
- Innovation

Run7: 1 mutation in exon of protein 4
07.01.2006

Run8 : 2 mutations in exon of protein 1
27

Example: Stability and Communication

Figure 1
Protein 1: - 10 %

Figure 2
Protein 1: - 100 %

Figure 3
Protein 1: - 300 %

Figure 4
Protein 1: + 200 %

Example: Stability and Communication II

Figure 5
Protein 7: + 200 %

Figure 6
Protein 7: - 200 %

Figure 7
Protein 3: + 300 %

Summary

- Simplicity of the model
- Stability of production
- Extraordinary evolutionary plasticity
- Similarity of behavior
- Time as an essential variable
